1 Getting Started

1.1 Welcome

Welcome to Variate Generator library!

By the time you have read through this tutorial, you will be able to play with it.

1.2 Compilation Environment Requirement

As some $C++11^*$ features are employed when implementing this library, before we get further, please check your compiler for C++11 compatablity.

1.3 A Quick Example

The code listed in Table 1 shows how to generate gaussian random numbers:

Table 1: Source Code for a Gaussian Variate Example

 $^{{\}rm *Features\ such\ as\ lambda\ functions,\ variadic\ template\ and\ keyword\ auto,\ see\ http://www.open-std.org/jtc1/sc22/wg21/\ for\ more\ information.}$

```
#include <vg.hpp>
#include <cmath>
#include <map>
#include <iostream>
int main()
{
    //generate double precision gaussian random numbers
    //using mt19937 as random generator engine with arguments (0,4)
    vg::variate_generator<double, vg::gaussian, vg::mt19937> vg(0, 4);
    std::map< int, int > sample;
    //generate 500 gaussian numbers and store them in a map
    for ( auto i = vg.begin(); i != vg.begin()+500; ++i )
        sample[std::round(*i)]++;
    //show the number generated
    for ( auto i = sample.begin(); i != sample.end(); ++i )
    {
        std::cout << (*i).first << "\t";
        for ( auto j = 0; j < (*i).second; ++j )
            std::cout << "\n";
        std::cout << "\n";
        }
        return 0;
}</pre>
```

As this library is header file only, if your c++ compiler is g++, a typical compilation and link command for the example code whose file name is $test_gaussian.cc$ can be

```
g++ - IPATH\_TO\_THE\_HEADER - o ./bin/gaussian\_test \ test\_gaussian.cc \ -std = c++11
```

This command will generate a executable file $gaussian_test$ in directory ./bin, and its executation result is shown in figure 1

2 An Overview of VG

A random variate generator consists of three parts:

- variate type
- ullet distribution type
- \bullet engine type

2.1 struct variate_generator

The basic struct used for a generator is variate_generator, which is decleared as:

```
iterator begin() const;
};
};
```

2.1.1 declaration

So to make a generator to product variates of int type and lagarithmic distribution, with a parameter 0.33, we can simply declare:

```
\label{eq:vg::variate_generator} $$ vg::lagarithmic> v( 0.33 ); $$ which it is equivalent to $$ vg::variate_generator<int, vg::lagarithmic, vg::mitchell_moore> v( 0.33, 0 ); $$ $$ vg::variate_generator<int, vg::lagarithmic, vg::mitchell_moore> v( 0.33, 0 ); $$ $$ $$ vg::variate_generator<int, vg::lagarithmic, vg::mitchell_moore> v( 0.33, 0 ); $$ $$ $$ vg::variate_generator<int, vg::lagarithmic, vg::mitchell_moore> v( 0.33, 0 ); $$ $$ $$ vg::variate_generator<int, vg::lagarithmic, vg::mitchell_moore> v( 0.33, 0 ); $$ $$ $$ vg::variate_generator<int, vg::lagarithmic, vg::mitchell_moore> v( 0.33, 0 ); $$ $$ $$ vg::variate_generator<int, vg::lagarithmic, vg::mitchell_moore> v( 0.33, 0 ); $$ $$ vg::variate_generator<int, vg::lagarithmic, vg::mitchell_moore> v( 0.33, 0 ); $$ $$ vg::variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:variate_generator<:var
```

where the last argument 0 is the default engine seed.

Also, to make a generator to product variates of hypergeometric distribution, with int type and parameters (200, 200, 200), using mt19937 persudo–random engine and engine seed 987654321, we can declare it with one line code like this:

```
vg::variate_generator<int, vg::hypergeometric, vg::mt19937> v( 200, 200, 200, 987654321 );
```

2.1.2 Generation

After the generator ν has been declared, we can generate variate in several ways:

Generate only one variate:

```
auto i = v();
int j = v;
auto k = *(v.begin());

Generate multiple variates:
std::vector<int> array1( v.begin(), v.begin()+100);
std::vector<int> array2( 100 );
std::generate( array2.begin(), array2.end(), v );
std::vector<int> array3;
std::copy( v.begin(), v.begin()+100, std::back.inserter( array3 ) );
```

2.2 Built-in Distributions

Curent we have about fifty distributions implemented:

- arcsine distribution
- bernoulli distribution
- beta distribution
- beta_binomial distribution
- beta_pascal distribution
- binomial distribution
- burr distribution

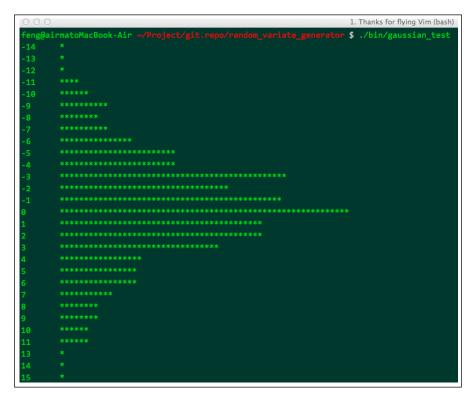

Figure 1: Gaussian Random Number Example

- cauchy distribution
- chi_square distribution
- digamma distribution
- \bullet erlang distribution
- exponential distribution
- exponential_power distribution
- ullet extreme_value distribution
- f distribution
- factorial distribution
- gamma distribution
- gaussian distribution
- $\bullet \ {\rm gaussian_tail} \ {\rm distribution}$
- generalized_hypergeometric_b3 distribution
- ullet generalized_waring distribution
- ullet geometric distribution
- $\bullet\,$ grassia distribution
- gumbel_1 distribution
- ullet gumbel_2 distribution
- ullet hyperbolic_secant distribution
- ullet hypergeometric distribution

- \bullet inverse_gaussian distribution
- ullet inverse_polya_eggenberger distribution
- lambda distribution
- laplace distribution
- levy distribution
- list distribution
- logarithmic distribution
- ullet logistic distribution
- ullet lognormal distribution
- mizutani distribution
- ullet negative_binomial distribution
- ullet negative_binomial_beta distribution
- normal distribution
- pareto distribution
- pascal distribution
- pearson distribution
- planck distribution
- poisson distribution
- $\bullet\,$ polya distribution
- $\bullet\,$ polya_aeppli distribution
- rayleigh distribution
- rayleigh_tail distribution
- $\bullet \ {\rm singh_maddala} \ {\rm distribution}$
- t distribution
- teichroew distribution
- ullet triangular distribution
- trigamma distribution
- uniform distribution
- \bullet von_mises distribution
- wald distribution
- waring distribution
- weibull distribution
- yule distribution
- zipf distribution

2.3 Engines

Currently we have 3 engines implemented:

- $\bullet \ \ linear_congruential$
- \bullet mitchell_moore
- mt19937

3 Distributions

3.1 Uniform Distribution

Generate pseudo random variables that uniformly distributed within interval [a, b].

3.1.1 Usage

```
Table 3: uniform distribution example code

#include <vg.hpp>
#include "test.hpp"

#include <vector>
#include <cstddef>

int main()
{
    vg::variate_generator<double, vg::uniform, vg::mt19937> vg_(-1, 1);
    std::size_t n = 100000000;
    std::vector<double> x(n);
    std::generate( x.begin(), x.end(), vg_ );
    test( x.begin(), x.end(), "unoform", 0, 1.0/12, 0.0, -2 );
    return 0;
}
```

3.1.2 Numeric Experiment

3.1.3 Description

 ssdsd

3.1.4 Characterization
